#### Abstract

Let *d* ≥ 2, *A* ⊂  $\mathbb{Z}^d$  be finite and not contained in a translate of any hyperplane, and  $q \in \mathbb{Z}$  such that  $|q| \geq 2$ . We show

 $|A + q \cdot A| \geq (|q| + d + 1)|A| - O(1)$ .

Keywords: higher dimensional sumsets, dilations.

msc: 11B13, 11B30, 11P70.

#### <span id="page-0-3"></span>1 Introduction

Let *A* and *B* be finite sets of real numbers. The sumset and the productset of *A* and *B* are defined by

$$
A + B = \{a + b \mid a \in A, b \in B\},\
$$
  

$$
A \cdot B = \{ab \mid a \in A, b \in B\}.
$$

For a real number  $d \neq 0$  the dilation of *A* by *d* is defined by

$$
d \cdot A = \{d\} \cdot A = \{da \mid a \in A\},\
$$

while for any real number *x*, the translation of *A* by *x* is defined by

<span id="page-0-1"></span>
$$
x + A = \{x\} + A = \{x + a \mid a \in A\}.
$$

The following (actually more) was shown in Balog and Shakan [\(n.d.\[a\]\)](#page-9-0).

**Theorem 1 (Balog and Shakan<sup>3</sup>) – Let**  $q \in \mathbb{Z}$ . Then there is a constant  $C_q$  such that *every finite A* ⊂ Z *satisfies*

<span id="page-0-0"></span>
$$
|A + q \cdot A| \ge (|q| + 1)|A| - C_q. \tag{1}
$$

This was obtained after the works of Bukh; Cilleruelo, Hamidoune, and Serra; Du S., Cao H., and Sun Z.; Hamidoune and Rué; Ljujic $^4$ . The reader is invited to see the introductions of Balog and Shakan [\(n.d.\[a\]\)](#page-9-0) and Bukh [\(2008\)](#page-10-0) for a more detailed introduction to this problem.

For a finite  $A\subset \mathbb{Z}^d$  , we say the *rank* of  $A$  is the smallest dimension of an affine space that contains *A*. When *A* is a set of high rank, one might expect to be able to improve the lower bound in equation [\(1\)](#page-0-0) on page [57,](#page-0-0) which is the goal of our current note. Ruzsa proved the following in Ruzsa [\(1994\)](#page-10-1).

**Theorem 2 (Ruzsa<sup>5</sup>)** – Let  $A, B \subset \mathbb{Z}^d$  be finite such that  $A + B$  has rank *d* and  $|A| \geq |B|$ . *Then*

<span id="page-1-0"></span>
$$
|A + B| \ge |A| + d|B| - \frac{d(d+1)}{2}
$$

Let *A* ⊂  $\mathbb{Z}^d$  be finite of rank *d* and *q* be an integer. The main objective here is to improve upon equation [\(1\)](#page-0-0) on page [57](#page-0-0) and theorem [2](#page-1-0) in the case  $B = q \cdot A$ . In this note *O*(1) will always depend on the relevant *d* and *q*. Our main theorem is the following.

**Theorem 3** − Let  $A ⊂ \mathbb{Z}^d$  of rank  $d ≥ 2$  and  $|q| ≥ 2$  be an integer. Then

<span id="page-1-1"></span> $|A + q \cdot A| \geq (|q| + d + 1)|A| - O(1)$ .

The authors would like to thank Imre Ruzsa for drawing our attention to the problem considered here. We remark that we do not believe even the multiplicative constant of  $(|q|+d+1)$  is the best possible, and we now present our best construction. For  $1 \le i \le d$ , let  $e_i$  be the standard basis vectors of  $\mathbb{Z}^d$ . For  $N \in \mathbb{Z}$ , consider

<span id="page-1-2"></span>
$$
A_N = \{e_1, \ldots, e_d\} \cup \{ne_1 / 0 < n < N \; , \; n \in \mathbb{Z}\}.
$$

An easy induction on *d* reveals

<span id="page-1-3"></span>
$$
|A_N + q \cdot A_N| \le (q + 2d - 1)|A_N| - (d - 1)(|q| - 2(d - 1) + 1)
$$
\n(2)

This shows that theorem [3](#page-1-1) is the best possible up to the additive constant for  $d = 2$ . We are also able to handle the case  $d = 3$ .

**Theorem 4** − *Let*  $A ⊂ \mathbb{Z}^3$  *be finite of rank* 3 *and*  $|q| ≥ 2$ *. Then* 

 $|A + q \cdot A| \geq (|q| + 5)|A| - O(1)$ .

<sup>5</sup>Ruzsa, [1994, "Sum of sets in several dimensions".](#page-10-1)

Furthermore, we can prove the following bound for all *q*, and this is best possible, up to the additive constant, when  $|q| = 2$ . One can check the example for equation [\(2\)](#page-1-2) on page [58](#page-1-2) to see that

$$
|A_N \pm 2 \cdot A_N| = (2d+1)|A_N| - d(d+1).
$$

<span id="page-2-0"></span>Theorem 5 – Let  $A ⊂ \mathbb{Z}^d$  be finite of rank *d* and  $|q| > 1$ . Then

 $|A + q \cdot A| \geq (2d + 1)|A| - d(d + 1)^2/2.$ 

Our basic intuition is that to minimize  $|A + q \cdot A|$  one should choose A to be as close to a one dimensional set as possible. One should proceed with caution with this intuition because when  $q = -1$ , a clever construction in Stanchescu [\(2001\)](#page-10-6) shows that this is not the best strategy. Nevertheless, given the evidence of theorem [4](#page-1-3) on page [58](#page-1-3) and theorem [5](#page-2-0) we present the following conjecture.

**Conjecture 1** − *Suppose*  $A ⊂ Z<sup>d</sup>$  *is finite of rank d and q is an integer with*  $|q| ≥ 2$ *. Then* 

<span id="page-2-1"></span>
$$
|A + q \cdot A| \ge (|q| + 2d - 1)|A| - O(1).
$$

We remark that the cases  $A + A$  and  $A - A$  have different behavior. Theorem [2](#page-1-0) on page [58,](#page-1-0) which in the case  $B = A$  was proved by Freiman<sup>6</sup>, says that  $|A + A| \ge$  $(d+1)|A|-d(d+1)/2$ . This is the best possible due to equation [\(2\)](#page-1-2) on page [58,](#page-1-2) which shows theorem [3](#page-1-1) on page [58](#page-1-1) is false with  $q = 1$ . The reason that one can improve when  $q \neq 1$  is simply that in  $A + A$ , the roles of the summands are interchangeable, while in the case  $A + q \cdot A$ , the roles of  $A$  and  $q \cdot A$  are not interchangeable. We have already mentioned that there is a tricky construction in Stanchescu [\(2001\)](#page-10-6), which shows |*A* − *A*| can be as small as  $(2d - 2 + \frac{1}{d-1})|A| - (2d^2 - 4d + 3)$ . In the same paper, the author conjectures that this is the best possible. It is curious that best known lower bound is  $|A - A|$  ≥  $(d + 1)|A| - d(d + 1)/2$ . The case  $q = −1$  is also different in the sense that it is important that when  $|q|$  > 1, we can split  $A$  into cosets modulo  $q \cdot \mathbb{Z}^d$ . This will be seen in our argument below.

Let  $L: \mathbb{Z}^d \to \mathbb{Z}^d$  be a linear transformation. In this note we are primarily concerned with  $|A + LA|$  where *L* is a scalar multiple of the identity. The study of other choices of *L* would be natural, but we do not do it here.

### <span id="page-2-2"></span>2 Proof of theorems [3](#page-1-1) and [5](#page-2-0)

Fix *A* ⊂  $\mathbb{Z}^d$  of rank *d* ≥ 2 and an integer *q* with  $|q|$  ≥ 2 Since the rank of *A* is *d*, we must have that *A* contains at least  $(d + 1)$  elements. We first partition *A* into its intersections with cosets of the lattice  $q \cdot \mathbb{Z}^d$  . Note there are  $|q|^{d}$  such cosets. Let

$$
A = \bigcup_{i=1}^{r} A_i, \ \ A_i = a_i + q \cdot A'_i, \ \ a_i \in \{0, \dots, |q| - 1\}^d, \ \ A'_i \neq \emptyset,
$$

<sup>6</sup>Freiman, [1973,](#page-10-7) *[Foundations of structural theory of set addition](#page-10-7)*.

where the unions are disjoint. We obtain the preliminary estimate

**Lemma 1** − *Let*  $A \subset \mathbb{Z}^d$  *and*  $q \in \mathbb{Z}$  *such that*  $|q| \ge 2$ *. Suppose that*  $A$  *intersects*  $r$  *cosets of the lattice q* · Z*<sup>d</sup> . Then*

$$
|A + q \cdot A| \ge (d+r)|A| - rd(d+1)/2.
$$

*Proof.* Using theorem [2](#page-1-0) on page [58,](#page-1-0) we obtain

$$
|A + q \cdot A| = \sum_{i=1}^{r} |A_i + q \cdot A|
$$
  
\n
$$
\geq \sum_{i=1}^{r} \left( d|A_i| + |A| - \frac{d(d+1)}{2} \right)
$$
  
\n
$$
= (d+r)|A| - rd(d+1)/2.
$$

We say that  $A$  is fully distributed (FD) modulo  $q \cdot \mathbb{Z}^d$  if  $A$  intersects every coset of  $q\cdot\mathbb{Z}^d$  . Note that for a  $\operatorname{\mathsf{FD}}$  modulo  $q\cdot\mathbb{Z}^d$  set, theorem [3](#page-1-1) on page [58](#page-1-1) and conjecture [1](#page-2-1) on page [59](#page-2-1) are far from optimal.

We now describe the process of reducing *A*. Applying an invertible linear transformation to *A* does not change  $|A + q \cdot A|$ . Suppose there is some  $a \in A$  such that the lattice  $\langle A-a\rangle_\mathbb{Z}=\Gamma$  is a non-trivial sublattice of  $\mathbb{Z}^d$  . Let  $L$  :  $\mathbb{Z}^d\to\mathbb{Z}^d$  be a linear transformation that maps the standard basis vectors to the basis vectors of Γ, that is  $\Gamma = L\mathbb{Z}^d$ . Since *A* has rank *d*, *L* is invertible. Then we may replace *A* with  $L^{-1}(A - a)$ . Note that  $L^{-1}(A - a) \subset \mathbb{Z}^d$  since  $A \subset a + L\mathbb{Z}^d$ . Since  $1 \leq \det(L) \in \mathbb{Z}$ , each reduction reduces the volume of the convex hull of *A* by at least  $\frac{1}{2}$ . The volume of the convex hull of *A* is always bounded from below by the volume of the *d*-dimensional simplex so eventually this process must stop. Thus we may assume  $\langle A - a \rangle_{\mathbb{Z}} = \mathbb{Z}^d$  for all *a* ∈ *A*. Then it follows that we have for all  $1 \le i \le r$ ,

<span id="page-3-0"></span>
$$
\mathbb{Z}^{d} = \langle A - a \rangle_{\mathbb{Z}} \subset \langle a_{1} - a_{i}, \dots, a_{r} - a_{i}, q e_{1}, \dots, q e_{d} \rangle_{\mathbb{Z}} \subset \mathbb{Z}^{d}.
$$
\n
$$
(3)
$$

Here we used that if  $x \in A - a$  and  $a \in A_i$ , then for some  $1 \leq j \leq r$  we have  $x \in A$  $a_j - a + q \cdot A'_j$ *j* ⊂  $\langle a_j - a_i, qe_1, \ldots, qe_d \rangle$ <sub>Z</sub>. We say *A* is *reduced* if equation [\(3\)](#page-3-0) holds.

*Proof (of theorem [5](#page-2-0) on page [59\)](#page-2-0).* By the discussion above, we may assume *A* is reduced. We first aim to show that a reduced set must intersect at least  $d + 1$  cosets of  $q\cdot\mathbb{Z}^{d}$  , and then we will appeal to the argument of lemma [1.](#page-3-1)

Observe that the linear combinations of  $a_1 - a_1, \ldots, a_r - a_1$  can only take at most |*q*| *<sup>r</sup>*−<sup>1</sup> different vectors mod *q* · Z*<sup>d</sup>* . Since *A* is reduced, by equation [\(3\)](#page-3-0), these vectors must intersect every coset modulo  $q \cdot \mathbb{Z}^d$ . Thus we have that  $|q|^{r-1} \geq |q|^d$ , and so  $r-1 \geq d$ .

<span id="page-3-1"></span>

#### 2. Proof of theorems [3](#page-1-1) and [5](#page-2-0)

Then by theorem [2](#page-1-0) on page [58,](#page-1-0) we find

$$
|A + q \cdot A| \ge \left(\sum_{i=1}^{d} |A_i + q \cdot A|\right) + \left|A \setminus \left(\bigcup_{i=1}^{d} A_i\right) + q \cdot A\right|
$$
  
\n
$$
\ge \left(\sum_{i=1}^{d} (d|A_i| + |A| - d(d+1)/2)\right) + d\left|A \setminus \left(\bigcup_{i=1}^{d} A_i\right)\right| + |A| - d(d+1)/2
$$
  
\n
$$
= (2d+1)|A| - d(d+1)^2/2.
$$

<span id="page-4-0"></span>We now focus our attention to the proof of theorem [3](#page-1-1) on page [58.](#page-1-1) We start with a special case. Recall that we assume  $d \geq 2$ .

**Lemma** 2 – *Suppose A is contained in d parallel lines. Then*  $|A + q \cdot A| \geq (|q| + 2d - 1)$  $1$ )| $A$ | –  $O(1)$ .

*Proof.* Suppose *A* is contained in  $x_1 + \ell, \ldots, x_d + \ell$  for some 1 dimensional subspace *l*. After a translation of *A* by −*a* for an element *a* ∈ *A* we can suppose  $x_1 = 0$  and without loss of generality, we may suppose  $x_2, ..., x_d$  are elements of  $\ell^{\perp} \cong \mathbb{R}^{d-1}$ . Moreover, we have that  $x_2, \ldots, x_d$  are linearly independent over  $\mathbb R$  since *A* has rank *d*. This implies that for all  $1 \le i, j \le d$ , the lines  $(x_i + \ell) + q \cdot (x_i + \ell)$  are pairwise disjoint. For  $1 \le i \le d$ , let  $B_i := A \cap (x_i + \ell)$ . It follows, using equation [\(1\)](#page-0-0) on page [57](#page-0-0) that

$$
|A + q \cdot A| = \sum_{i=1}^{d} \sum_{j=1}^{d} |B_i + q \cdot B_j|
$$
  
= 
$$
\sum_{i=1}^{d} \left( |B_i + q \cdot B_i| + \sum_{j \neq i} |B_i + q \cdot B_j| \right)
$$
  

$$
\geq \sum_{i=1}^{d} \left( \left( (|q| + 1)|B_i| - O(1) \right) + \sum_{j \neq i} (|B_i| + |B_j| - 1) \right)
$$
  
= 
$$
(|q| + 2d - 1)|A| - O(1).
$$

We remark that the lack of a satisfactory higher dimensional analog of lemma [2](#page-4-0) is essentially what blocks us from improving the multiplicative constant in m theorem [3](#page-1-1) on page [58.](#page-1-1)

We prove theorem [3](#page-1-1) on page [58](#page-1-1) by induction on  $d$  starting from  $d = 2$  (the statement is not true for  $d = 1$ ). Note that the proof of the next lemma does not use the induction hypothesis for  $d = 2$  but only for  $d \geq 3$ .

**Lemma 3** − Let  $B \subset A$  *and suppose that the rank of*  $B$  *is*  $1 \le f \le d$ *. Then* 

<span id="page-4-1"></span>
$$
|B + q \cdot A| \ge (|q| + d + 1)|B| - O(1),
$$

*or A is contained in d parallel lines.*

Sum of dilates in vector spaces Theorem A. Balog and G. Shakan

*Proof.* Note that the rank of  $B + q \cdot B$  is also f. Since  $B + q \cdot A$  is of rank *d*, we may find an  $x \in A$  such that  $B + qx$  is not in the affine span of  $B + q \cdot B$ . Thus  $B + q \cdot B$  and  $B + qx$ are disjoint. The rank of  $B \cup \{x\} + q \cdot (B \cup \{x\})$  is  $f + 1$ . We may repeat this process with  $B \cup \{x\} + q \cdot (B \cup \{x\})$  in the place of  $B + q \cdot B$ , and so on, a total of  $(d - f)$  times. Thus we find  $x_1, ..., x_{(d-f)}$  ∈ *A* such that  $B + q \cdot B$ ,  $B + qx_1, ..., B + qx_{(d-f)}$  are pairwise disjoint. When  $f \ge 2$  (so  $d \ge 3$  $d \ge 3$ ) we use the induction hypothesis, that is theorem 3 on page [58](#page-1-1) for the sum  $B + q \cdot B$  where *B* is of rank  $2 \le f \le d$  to get

$$
|B + q \cdot A| \ge |B + q \cdot B| + \sum_{j=1}^{d-f} |B + qx_j| \ge (|q| + d + 1)|B| - O(1).
$$

Now we handle the case  $f = 1$  (this is the only possibility when  $d = 2$ ), in this case we do not use the induction hypothesis. *B* is contained in a line. We may suppose *A* is not contained in *d* parallel lines. We proceed as above to find *x*1*,..., xd*−<sup>1</sup> such that  $B + q \cdot B$ ,  $B + qx_1$ ,...,  $B + qx_{(d-1)}$  are pairwise disjoint. Since *A* is not contained in *d* parallel lines, we may find an  $x_d \in A$  such that  $B + qx_d$  is disjoint from all  $B + q \cdot B$ ,  $B + qx_1, \ldots, B + qx_{(d-1)}$ . It follows from theorem [1](#page-0-1) on page [57](#page-0-1) applied to the sum  $B + q \cdot B$  that

$$
|B + q \cdot A| \ge |B + q \cdot B| + \sum_{j=1}^{d} |B + qx_j| \ge (|q| + d + 1)|B| - O(1).
$$

<span id="page-5-0"></span>The next lemma is a higher dimensional analog of Lemma 3.1 in Balog and Shakan  $(n.d.[a])$ .

**Lemma** 4 – Let  $1 \leq i \leq r$ . Then either  $A_i'$  $\int_{i}^{t}$  *is* FD modulo  $q \cdot \mathbb{Z}^{d}$  or

$$
|A_i + q \cdot A| \ge |A_i + q \cdot A_i| + \min_{1 \le w \le r} |A_w|.
$$

*Proof.* Suppose

$$
|A_i + q\cdot A| < |A_i + q\cdot A_i| + \min_{1\leq w\leq r} |A_w|.
$$

Fix 1 ≤ *w* ≤ *r*. Since  $A_w$  ⊂ *A*, we find that

$$
|(A_i + q\cdot A_w) \setminus (A_i + q\cdot A_i)| < |A_w|.
$$

Translation by  $-a_i$  and dilation by  $\frac{1}{q}$  reveals that

$$
|(a_w-a_i+A'_i+q\cdot A'_w)\setminus (A'_i+q\cdot A'_i)|<|A'_w|.
$$

Thus for any  $x \in A'_i$ *i*<sub>i</sub> there is a *y* ∈ *A*<sup>*w*</sup><sub>*w*</sub> such that  $a_w - a_i + x + qy$  ∈ *A*<sup>*i*</sup><sub>*i*</sub>  $i + q \cdot A_i'$ *i* . It follows that there is a  $x' \in A'_i$ *i*<sub>i</sub> such that  $a_w - a_i + x \equiv x' \mod q \cdot \mathbb{Z}^d$ . We may repeat this argument with  $x'$  in the place of  $x$ , and so on, and for each  $1 \leq w \leq r$  to obtain that for any  $u_1, \ldots, u_r \in \mathbb{Z}$  there is a  $x'' \in A_i'$  $i$ <sub>i</sub> such that

$$
u_1(a_1-a_i)+\cdots+u_r(a_r-a_i)+x\equiv x'' \mod q \cdot \mathbb{Z}^d.
$$

Since *A* is reduced, this describes all of the cosets modulo  $q \cdot \mathbb{Z}^d$  and it follows that  $A_i'$  $\int_{i}$  is  $f$  mod  $q \cdot \mathbb{Z}^{d}$ . The contract of the contract

We are now ready to prove theorem [3](#page-1-1) on page [58.](#page-1-1) We start with  $|A + q \cdot A| \geq |A|$  and improve upon the multiplicative constant iteratively.

**Proposition 1** – *Suppose*  $A \subset \mathbb{Z}^d$  *such that*  $A$  *has rank*  $d$ *. Let*  $q \in \mathbb{Z}$  *such that*  $|q| \geq 2$ *. Then for every*  $|q| + d + 1 \le m \le (|q| + d + 1)^2$ , one has

<span id="page-6-0"></span>
$$
A + q \cdot A \ge \frac{m}{|q| + d + 1} |A| - O(1),
$$

*where O*(1) *also depends on m.*

*Proof.* Observe that  $m = (|q| + d + 1)^2$  is precisely theorem [3](#page-1-1) on page [58.](#page-1-1) For convenience, set  $S = |q| + d + 1$ . We prove by induction on *m*, where  $|A + q \cdot A| \ge |A|$  trivially starts the induction. Suppose now that proposition [1](#page-6-0) is true for a fixed  $S \le m < S^2$ , and we prove it for  $m + 1$ .

If *A* is contained in *d* parallel lines, then lemma [2](#page-4-0) on page [61](#page-4-0) immediately implies theorem [3](#page-1-1) on page [58,](#page-1-1) and so proposition [1](#page-6-0) is especially true for *m* + 1 as well. Thus we may assume *A* is not contained in *d* parallel lines.

Consider a set  $B \subset A$ . If it is  $1 \le f < d$  dimensional, then lemma [3](#page-4-1) on page [61](#page-4-1) shows that  $|B + q \cdot A| \geq S|B| - O(1)$ . If *B* is *d* dimensional, then by the induction hypothesis on *m*, we have

 $|B + q \cdot A| \ge |B + q \cdot B| \ge \frac{m}{S}|B| - O(1)$ . In either case, using that  $m < S^2$ , we have

<span id="page-6-1"></span>
$$
|B + q \cdot A| \ge \frac{m}{S}|B| - O(1). \tag{4}
$$

First, assume there is an  $1 \le i \le r$  such that  $|A_i| \le \frac{1}{S}|A|$ . We have by equation [\(4\)](#page-6-1) and theorem [2](#page-1-0) on page [58,](#page-1-0) that

$$
|A + q \cdot A| \ge |A_i + q \cdot A| + |(A \setminus A_i) + q \cdot A| \ge
$$
  
 
$$
\ge |A_i| + |A| - 1 + \frac{m}{S}(|A| - |A_i|) - O(1) \ge \frac{m+1}{S}|A| - O(1).
$$

Thus we may assume that every  $A_i$  has more than  $\frac{1}{S}$  |A| elements.

Suppose now that every  $A_i$  is strictly less than  $d$  dimensional. Then lemma [3](#page-4-1) on page [61](#page-4-1) shows that

$$
|A + q \cdot A| = \sum_{i=1}^{r} |A_i + q \cdot A| \ge \sum_{i=1}^{r} ((|q| + d + 1)|A_i| - O(1))
$$
  
=  $(|q| + d + 1)|A| - O(1) \ge \frac{m+1}{S}|A| - O(1).$ 

Thus we may assume that there is an  $A_i$  that is  $d$  dimensional.

If the corresponding  $A_i'$  $\mathbf{z}'_i$  is not rp modulo  $q \cdot \mathbb{Z}^d$ , then by lemma [4](#page-5-0) on page [62,](#page-5-0) equation [\(4\)](#page-6-1) on page [63,](#page-6-1) and by the induction hypothesis for  $A_i$  we have

$$
|A + q \cdot A| \ge |A_i + q \cdot A| + |(A \setminus A_i) + q \cdot A|
$$
  
\n
$$
\ge |A_i + q \cdot A_i| + \min_{1 \le w \le r} |A_w| + \frac{m}{S}(|A| - |A_i|) - O(1)
$$
  
\n
$$
\ge \frac{m}{S}|A_i| - O(1) + \frac{1}{S}|A| + \frac{m}{S}(|A| - |A_i|) - O(1) = \frac{m+1}{S}|A| - O(1).
$$

Similarly if  $A_i'$  $\int_{i}^{i}$  is  $\pi$  mod  $q \cdot \mathbb{Z}^{d}$  (and  $A_{i}$  is *d* dimensional) then by lemma [1](#page-3-1) on page [60](#page-3-1) and equation [\(4\)](#page-6-1) on page [63](#page-6-1) we have

$$
|A + q \cdot A| = |A_i + q \cdot A| + |A \setminus A_i + q \cdot A| \ge |A'_i + q \cdot A'_i| + |A \setminus A_i + q \cdot A|
$$
  
\n
$$
\ge (|q|^d + d)|A'_i| - O(1) + \frac{m}{S}(|A| - |A_i|) - O(1) \ge \frac{m+1}{S}|A| - O(1).
$$

Note that the only place where we have used the hypothesis of the induction on *d* is the  $f \ge 2$  case of the proof of lemma [3](#page-4-1) on page [61,](#page-4-1) what we do not use when  $d = 2$ thus this argument also proves theorem [3](#page-1-1) on page [58](#page-1-1) in that case.

### <span id="page-7-0"></span>3 Proof of theorem [4](#page-1-3)

Let *A* ⊂  $\mathbb{Z}^3$  of rank 3 and *q* be a positive integer such that  $|q| \ge 2$ .

The proof of theorem [4](#page-1-3) on page [58](#page-1-3) is almost identical to that of theorem [3](#page-1-1) on page [58.](#page-1-1) The only difference is that we have to strengthen lemma [2](#page-4-0) on page [61.](#page-4-0) The reader is invited to check that it is enough to prove lemma [2](#page-4-0) on page [61](#page-4-0) in the case where  $d = 3$  and A is contained in two parallel planes or 4 parallel lines and then the proof of theorem [3](#page-1-1) on page [58](#page-1-1) goes through in an identical manner. Indeed, if one was able to prove conjecture [1](#page-2-1) on page [59](#page-2-1) in the special cases for each 1 ≤ *f* ≤ *d* − 1, and *A* is contained in 2(*d* − *f* ) translates of a *f* -dimensional subspace, then this along with the proof of theorem [3](#page-1-1) on page [58](#page-1-1) would imply conjecture [1](#page-2-1) on page [59](#page-2-1) in general.

Lemma 5 – *Suppose A is contained in two parallel hyperplanes. Then*

 $|A + q \cdot A| \geq (|q| + 5)|A| - O(1)$ .

*Proof.* Suppose  $A \subset H \cup (H + x)$  for some hyperplane *H* and some  $x \in \mathbb{Z}^3$ . Since  $|q| > 1$ , we have that

$$
(H+q\cdot H),(H+x+q\cdot H),(H+q\cdot (H+x)),((H+x)+q\cdot (H+x)),
$$

#### 3. Proof of theorem [4](#page-1-3)

are disjoint Let  $B_1 = H \cap A$  and  $B_2 = (H + x) \cap A$ . Then we have that

<span id="page-8-0"></span>
$$
|A + q \cdot A| \ge |B_1 + q \cdot B_1| + |B_1 + q \cdot B_2| + |B_2 + q \cdot B_1| + |B_2 + q \cdot B_2|.
$$
 (5)

Suppose, without loss of generality, that  $|B_1| \geq |B_2|$ . We separately consider several cases.

- 1. Suppose  $B_1$  has rank 2. Then by theorem [3](#page-1-1) on page [58,](#page-1-1) we have  $|B_1 + q \cdot \mathbf{r}|$  $B_1 \geq (|q| + 3)|B_1| - O(1)$ . Furthermore by theorem [2](#page-1-0) on page [58,](#page-1-0) we have  $|B_1 + q \cdot B_2| + |B_2 + q \cdot B_1| \geq 2(|B_1| + 2|B_2| - 3)$ . Lastly, by equation [\(1\)](#page-0-0) on page [57,](#page-0-0) we have  $|B_2 + q \cdot B_2|$  ≥  $(|q|+1)|B_2|$  − *O*(1). Combining this three inequalities with equation [\(5\)](#page-8-0) yields  $|A + q \cdot A| \geq (|q| + 5)|A| - O(1)$ . Note that this case applies when  $B_2$  consists of a single point.
- 2. Suppose  $B_1$  has rank 1 and  $B_2$  has rank 2. By equation [\(1\)](#page-0-0) on page [57,](#page-0-0)  $|B_1 + q \cdot$ *B*<sub>1</sub>|≥ (|*q*|+1)|*B*<sub>1</sub>|−*O*(1) and by theorem [3](#page-1-1) on page [58,](#page-1-1)  $|B_2 + q \cdot B_2|$ ≥ (|*q*|+3)|*B*<sub>2</sub>|− *O*(1). We have that  $B_1$  lies in a translate of some line, say  $\ell$ . Suppose  $B_2$  lies in some distinct lines  $x_1 + \ell, \ldots, x_m + \ell$  such that each  $x_i + \ell$  intersects  $B_2$  in at least one point. Note that  $m \ge 2$  since *A* has rank 3. For each  $1 \le j \le m$ , let  $B_2^j = B_2 \cap (x_j + \ell)$ . Then by the one dimensional theorem [2](#page-1-0) on page [58,](#page-1-0) we have

$$
|B_1 + q \cdot B_2| \ge \sum_{j=1}^m |B_1 + q \cdot B_2^j| \ge m|B_1| + \sum_{j=1}^m (|B_2^j| - 1) \ge 2|B_1| + |B_2| - 2.
$$

Similarly,  $|B_2 + q \cdot B_1| \geq 2|B_1| + |B_2| - 2$ . Combining these four inequalities with equation [\(5\)](#page-8-0), we obtain  $|A + q \cdot A| \geq (|q| + 5)|A| - O(1)$ .

3. Suppose  $B_1$  and  $B_2$  are both rank 1. Then the sets  $x + q \cdot B_1$  and  $B_1 + q \cdot x$  where  $x \in B_2$  are all disjoint. Using equation [\(1\)](#page-0-0) on page [57,](#page-0-0) we obtain (the extremal case being  $|B_2| = 2$ )

$$
|A + q \cdot A| \ge (|q| + 1)|A| - O(1) + 2|B_1||B_2| \ge (|q| + 5)|A| - O(1).
$$

We now have to consider the case where *A* is contained in four parallel lines.

Lemma 6 – *Suppose A is contained in four parallel lines. Then*

 $|A + q \cdot A| \geq (|q| + 5)|A| - O(1)$ .

*Proof.* Suppose *A* is contained in four parallel lines, all parallel to some line through the origin  $\ell$ . Then  $\mathbb{Z}^3/\ell \cong \mathbb{Z}^2$  and say  $A' = \{x_1, x_2, x_3, x_4\} \subset \mathbb{Z}^3/\ell$  are the 4 cosets that intersect *A*. Note that *A'* must be a 2 dimensional set since *A* is 3 dimensional. We want to show  $|A' + q \cdot A'| \ge 14$  $|A' + q \cdot A'| \ge 14$  $|A' + q \cdot A'| \ge 14$ . By the argument of lemma 1 on page [60,](#page-3-1) we may assume that *A'* intersects at least 3 residue classes modulo  $q \cdot (\mathbb{Z}^3 / \ell)$ . If *A'* 

intersects four residue classes, then  $|A' + q \cdot A'| = 16$ . Otherwise let  $A'$  $\frac{7}{1}$  be the intersection of  $A'$  with the residue class that contains 2 elements of  $A'$ . Since  $A'$  is 2 dimensional, it is not an arithmetic progression, so  $|A_{1}^{\prime}|$  $|A'_1 + q \cdot A'| \ge |A'_1|$  $|A'| = 6$ . Then  $|A' + q \cdot A'| = 8 + |A|$  $|q \cdot A'| \ge 14.$ 

Let *A* = *B*<sub>1</sub> ∪ ··· ∪ *B*<sub>4</sub> where *B*<sub>*i*</sub> = ( $\ell$  + *x*<sub>*i*</sub>) ∩ *A*. Then *B*<sub>*i*</sub> + *q* · *B*<sub>*j*</sub> are all disjoint, if we drop at most two pairs {*i, j*}. We do not need to drop a pair in the form {*i, i*} because an equation in the form  $x_i + qx_i = x_j + qx_j$  is not possible in *A*'. That means, any set  $B_i$  can appear in a dropped pair at most twice. Then

$$
|A + q \cdot A| \ge \sum_{i=1}^{4} |B_i + q \cdot B_i| + \sum_{\substack{i \ne j \\ \text{not dropped}}} |B_i + q \cdot B_j|
$$
  
\n
$$
\ge \sum_{i=1}^{4} ((|q| + 1)|B_i| - O(1)) + \sum_{i \ne j} (|B_i| + |B_j| - 1) - 2|A| = (|q| + 5)|A| - O(1).
$$

Finally we can express the analog of lemma [3](#page-4-1) on page [61.](#page-4-1) Note that the proof uses theorem [3](#page-1-1) on page [58](#page-1-1) and theorem [1](#page-0-1) on page [57](#page-0-1) rather than any induction, otherwise identical to the proof of lemma [3](#page-4-1) on page [61.](#page-4-1)

**Lemma** 7 – Let  $A \subset \mathbb{Z}^3$  of rank 3,  $B \subset A$  and suppose that the rank of B is  $1 \le f < 3$ . *Then*

$$
|B + q \cdot A| \ge (|q| + 5)|B| - O(1),
$$

*or A is contained in two parallel hyperplanes or in four parallel lines.*
